

**DEEP SEA CREATURE**—A possibly new species of crinoid is shown here as it was caught in a photograph of a ledge of a newly-discovered cliff in the Gulf of Mexico. Due to fouling of the tripper weight, the camera is presumed to have fired late—almost horizontally; the angle of sea bottom slope is estimated as 45 degrees. The foot-long, branched object in the foreground is the crinoid. The far ridge, with stalked crinoids, is believed to be about 15 feet from the camera.

## Earlier Cancer Detection

Better and quicker detection of cancer expected through new apparatus to be used with Papanicolaou smear test. Device makes cancer cells show themselves.

➤ EARLIER DETECTION of cancer with consequent saving of lives should be possible in many more cases through a device developed by Drs. Robert C. Mellors and Reuben Silver of Sloan-Kettering Institute for Cancer Research, Memorial Center, New York.

The device is called a microfluorometric scanner for the differential detection of cancer cells. It was developed to be used with the famous Papanicolaou smear test. The Papa test, as it is known for short, takes advantage of the fact that cancers, even very early, small ones, shed cells as trees shed leaves. These exfoliated cancer cells can be found in the secretion or fluids from the organ where the cancer is.

In using the Papa test, the fluid is smeared on a glass slide, stained with appropriate dyes, and examined under the microscope.

Trained pathologists can recognize the cancer cells. One drawback to wider use of the Papa test for early detection of cancer is the need for persons with special training in recognizing the cancer cells.

The new device, reported in the journal, *SCIENCE* (Oct. 5), makes the cancer cells show themselves in a practically automatic way. It is based on the fact that when cells are stained with a basic fluorescent dyestuff, cancer cells combine with more of the dye than normal cells. When longwave ultraviolet light is shone on the stained cells, each cell shines but the cancer cells shine brighter.

The light the cells give off can be measured with a microphotometer. With the aid of an electronic counting circuit, the presence of certain types of cells can be made to register according to the light they are emitting.

Drs. Mellors and Silver hope that their instrument will make easier large scale screening of the population for cancer, particularly cancer of the uterus in early stages when proper treatment brings a high rate of cure.

Cells shed by lung cancers and found in the pleural fluid also show a quantitative difference from normal cells in the amount of the fluorescent dye they combine with and consequently in the amount of light they give off under ultraviolet. Whether the same is true for cancer cells from stomach, intestines and other parts of the body has not yet been determined.

## Discover Possible New Species of Crinoid in Gulf

➤ A POSSIBLE new species of crinoids, strange creatures somewhat related to starfish, has been discovered in the Gulf of Mexico.

Crinoids usually live rooted in the ooze or mud of the sea bottom, but this foot-high specimen was photographed attached to what appears to be hard rock on the ocean floor. It was found during a survey of the Caribbean area by the Woods Hole Oceanographic Institution's research vessel *Atlantis*.

The picture disclosing the new crinoid was taken of a ledge of a steep cliff, some 70 miles off the west Florida coast, discovered during the survey. Dr. Austin Clark of the Smithsonian Institution states that the crinoid is possibly "something quite new, as none of the stalked crinoids living attached to rocks by a terminal stem plate have so far been found in the Atlantic basin."

## Disease-Causing Viruses Aid Battle Against Cancer

➤ STRANGE DISEASE-causing viruses from Africa and South America are now being used in the battle against cancer.

Almost 100 cancer patients at Memorial Hospital in New York City have been given this virus-against-cancer treatment during the past two years.

The treatment has not yet produced any cures. In fact, the doctors there "don't think we have ever done any patients any good," one of them said. But they keep on trying in the hope of hitting a virus that will do the job of killing cancer cells without harming normal cells.

This approach, selective killing of cancer cells, offers the best solution to the cancer problem, Dr. Geoffrey Hadfield, professor of pathology at the Royal College of Surgeons, London, declared at the meeting
