

Loving lizards: Sex and unisex species

Courtship and mating behaviors may be more widespread than the mixing of genes by sexual reproduction. "We report for the first time evidence indicating that although unisexual *Cnemidophorus* lizards have dispensed with genetic sex, behavioral sex continues," says David Crews of Harvard University.

At least 27 species of reptiles are made up entirely or almost entirely of females reproducing parthenogenetically, so that each daughter is genetically identical to her mother. Scientists collected members of three such lizard species from Arizona and Colorado and found that pairs of females of these species (but not of closely related sexual species) behave in a manner resembling mating.

The "sexual" behavior of the parthenogenetic females includes courtship and copulatory phases. One animal lunges at another and bites her on the tail, then mounts the back and rides atop for a minute or two, while stroking the back and neck with her jaws and forelimbs and rubbing her cloaca (the female lizard's combined reproductive and excretory opening) against the back. The top lizard grasps the back of the neck or shoulder in her jaws and curves her tail beneath the other's tail to appose the cloacal regions. Finally she shifts her jaw grip further down the body to achieve the contorted mating posture characteristic of that genus of lizard. The females maintain the position 1 to 5 minutes, until the bottom animal breaks away.

Age and size do not determine the lizards' sexual role. Which female is top and which is bottom is a matter of the ovulatory cycle, Crews and Kevin T. Fitzgerald of the University of Colorado find. In each of 17 pseudo-matings, the more aggressive, courting animal contained only small, undeveloped follicles in her ovaries and was either post-ovulatory or reproductively inactive. The more passive member of the pair always had large, yolky preovulatory follicles, and laid her eggs about 30 days later. Crews and Fitzgerald have seen the same lizard play both sexual roles.

The scientists do not yet know what makes the preovulatory female sexually attractive. Estrogen administered to females at other stages of their cycle does not make them attractive, although the allure may come from an estrogen-progesterone interaction. Crews suspects that chemicals emitted by the preovulatory female play a role, because the lizards have scent pores along their hind legs and inspect each other with much tongue-flicking activity.

The courting behavior seems to be more than a nonfunctional vestige of the lizard species' sexual ancestry. Crews says

Mounting and contorted mating posture of all-female Cnemidophorus uniparens (upper photos) closely resemble those of sexual species C. tigris (lower photos).

the behavior primes some hormonal mechanism that regulates the ovaries' activity. Animals caged alone do reproduce, but they lay eggs at longer intervals than do animals raised in groups.

So far the scientists have no idea of the ecological significance of the sexual behavior. The lizards live in large groups in burrows and are fast-moving. "In the wild, we never saw anything other than biting and chasing. We don't know what's going on in those tunnels," Crews says.

In current work, Crews and collaborators are treating the eggs of parthenogenetic lizards with hormones to try to create males. Crews says that they have already had some success in that the gonads of hatchlings of some treated eggs have a male-like duct system. "This could be the most dramatic research," Crews says. In essence they may be turning their lizards from parthenogenesis back to two-sex reproduction. □

Ozone depletion: Death to shellfish?

While the earth is expected to lose an estimated 16.5 percent of its ozone layer over the next 100 years (SN: 11/17/79, p. 340), it appears that *current* stratospheric ozone levels may already be dangerously close to damaging certain marine life environments. Scientists at the National Marine Fisheries Laboratory in Manchester, Wash., report that above a certain "threshold level" of exposure to ultraviolet radiation, the survival rates of shrimp and crab larvae decline rapidly.

The experimental threshold of UV-B — the middle portion of the ultraviolet spectrum that is partially filtered out by the ozone — is near the levels that shellfish already experience in their natural environment, according to David Damkaer of the fisheries lab, which is part of the National Oceanic and Atmospheric Administration. Shrimp and crab larvae already are "living close to the thin edge of survival," Damkaer says.

The shellfish larvae generally inhabit ocean surface waters in the late winter and early spring. Although the UV-B radiation reaches its peak in July — when it exceeds the tolerance level determined in the study — NOAA scientists note that UV-B levels are close to or above the danger threshold by the end of the surface season of each species. The effect of ozone depletion, Damkaer and his colleagues suggest, would be to admit more UV-B earlier in the season, shortening the creatures' "safe" time in surface waters.

"Whether or not the populations could endure with a drastically reduced time of near-surface occurrence is not known," Damkaer says. "The way things look, if ultraviolet increases, we're going to see the populations of some species die out. This is serious. And it's dollars and cents to the fishermen of this state and anywhere else where the environment might become inhospitable to shellfish." □

Hopkins heart disease advances

What biomedical advances can a specific amount of money buy? One answer to this rarely posed but eminently practical question was given last week at a science writers' conference at the Johns Hopkins Medical Institutions in Baltimore. Investigators in John Hopkins's cardiology division described some recent advances they have made with \$8 million in government and university funds.

• Several years ago Duke University researchers invented two-dimensional ultrasound, which uses high-frequency, pulsed sound to display several areas of

... Heart disease

the heart at one time. James Weiss and co-workers at Johns Hopkins used two-dimensional ultrasound to examine the hearts of 30 patients who had had heart attacks, and found that eight of the patients incurred expansion of their heart walls following the attacks. Four of these eight died, but none of the 22 without heart wall expansion did. So Weiss and his team conclude that heart wall expansion after a heart attack is potentially lethal and are trying to see whether drugs can prevent it.

• Half a million persons in the United States die suddenly each year because the ventricles of their hearts beat arrhythmi-

cally, then stop. Most victims have no way of suspecting that they may be susceptible to fatal ventricular arrhythmias, nor do their physicians. But now Philip Reid and his colleagues at Johns Hopkins have developed simple, safe and accurate means of predicting fatal ventricular arrhythmias. They apply a small electrical stimulus directly to the hearts of human subjects through a cardiac catheter and find that those subjects whose ventricles go into arrhythmias in response to the stimulus are most in danger of sudden death from ventricular arrhythmias. Reid and his team are now looking at ways to make the test more reliable and are trying

to develop less invasive ways to give the stimulus. One possibility is a modified staple gun that delivers a relatively painless mechanical thump to the chest.

• Thallium imaging of the heart consists of injecting thallium, a radioactive substance, into the bloodstream and then using a camera to visualize its arrival in the heart. However, if heart muscle has died as the result of a heart attack, neither blood nor thallium can penetrate it. So Lewis Becker and his colleagues at Johns Hopkins attempted to determine whether thallium imaging might predict which heart attack patients have a poor prognosis — that is, whether those patients with a severe reduction of blood and thallium to the heart are at the greatest risk of death. They find that this is indeed the case and they have developed a computer scoring method based on heart attack patients who did well for a year after their attacks and on patients who died within a year of their attacks. This scoring method was tested prospectively on 93 heart attack patients. Fifteen were given high-risk scores and 78 low-risk scores. Fifty-three percent of the high-risk patients later died, but only eight percent of the low-risk patients did. Becker and his co-workers conclude that thallium imaging “is a very powerful tool” for determining whether heart attack patients are at high risk. □

Johns Hopkins

Two-dimensional ultrasound, which is delivered to a patient by Johns Hopkins technologist Sandy O'Malley, has revealed that heart wall expansion after a heart attack is not uncommon and that if it occurs, it is potentially lethal.

CALLIGRAPHY, THE ART OF LETTERING WITH THE BROAD PEN — by Byron J. Macdonald

This book, one of the classics in the lettering arts field, presents 26 alphabets and variations, from the basic Roman capitals through Uncial, Gothic, Batarde and Italic hands with explanations of their appropriate applications. Plates are large and so crisply printed that students, with guidance from the text, can easily see the architecture and character of each letter form. The style and format of the book make it an ideal companion to Lloyd Reynolds's book. Spiral bound for convenience. 6th printing. Paper Cover \$4.95

ITALIC CALLIGRAPHY & HANDWRITING — by Lloyd Reynolds

This is far and away the most popular book in the field. Now in its seventeenth printing, it takes the reader through every stage in studying Italic handwriting and calligraphy with a clear text and 23 full page plates. Separate sections on Roman capitals as well as page and book designs make this a complete course. Spiral bound for convenience in use. Paper Cover \$3.95

Calligraphy
 is the most direct form of all artistic expression
 JUST AS EACH MOVEMENT
 OF THE DANCER IS ABSOLUTE
 SO EVERY GESTURE
 OF THE CALLIGRAPHER
 IS ESSENTIAL
 IT IS NOT THE MEANING OF THE
 CHARACTER BUT THE WRITING—
 THE MOVEMENT OF EXECUTION
 AND THE ACTION ITSELF—
 THAT IS IMPORTANT
