Subscription Department
231 West Center Street, Marion, Ohio 43305

Subscription rate: 1 yr., \$34.50; 2 yrs., \$58.00.
(Foreign postage \$6.00 additional per year.) Change of
address: Four to six weeks' notice is required. Please
state exactly how magazine is to be addressed.
Include zip code. For new subscriptions only call
(1) 800-247-2160. Printed in U.S.A. Second class
postage paid at Washington, D.C., and additional
mailing offices. Title registered as trademark U.S. and
Canadian Patent Offices. Published every Saturday by
SCIENCE SERVICE, Inc., 1719 N St., N.W.,
Washington, D.C. 20036. (202-785-2255)
ISSN 0036-8423

Creating a Venus

Thank you for continuing to cover mathematical as well as physical science news. The story on homotopies of Boy's surface ("Twists of Space," SN: 10/24/87, p.264) was particularly delightful, thanks to the superb new graphics.

I would like to point out one error and one omission in this story. Reporter Ivars Peterson gives the erroneous impression (due to an ambiguous "It" reference) that the Etruscan Venus form "can be created by gluing together two Möbius strips." It cannot; that is how to create a three-dimensional Klein bottle, and the Etruscan Venus — like all the other surfaces shown in the article — is a shadow of a four-dimensional Klein bottle. The Etruscan Venus form is thus in no way distinguished from the others by this property, or else there would not exist the pos-

Articles

- 344 Organic Origami

Cover: Scientists are trying to learn the fundamental rules that dictate the three-dimensional structures of proteins. Using computer imaging, they are learning how to design biologically useful proteins that might not otherwise occur in nature. Here, a molecule of the cancer-killing drug methotrexate (green skeletal structure) is shown nestled in the active site of an enzyme critical to cell reproduction. Misguided loyalty?

Your story on the Woodruff-Teller controversy over the viability of X-ray lasers ("Star Wars Lasers: A Question of Technical Integrity," SN: 10/31/87, p.276) is some evidence that scientists are not immune to two disturbing tendencies now widespread in other professions.

One is a tendency for loyalty to an intellectual ideal to become transmuted into political attachment to institutions supposed to embody that ideal. In lawyers, a commitment to the ideal of law becomes an instinctive allegiance to lawless judicial institutions. Similarly, Dr. Woodruff's dedication to science seems to have made him reluctant to betray an institution even when it engages in suppression of scientific truth.

Matters are made much worse when these parochial professional allegiances are cou-

pled with a contempt for the democratic ideal. Lawyers regard the electorate as a salivating mob that requires a judicial oligarchy to defend it from itself. Similarly, Dr. Woodruff sees his duty as one that runs to unnamed "policymakers in government," not to his fellow citizens.

At the risk of seeming unkind or naive, I suggest that scientists, like lawyers, need to frequently remind themselves that the events of 1776 require us to put our trust in our fellow citizens, not King Ronnie, the Barons of The Bench or the Dukes of DOE.

Burning question

"Forest Fires, Barnacles and Trickleing Oil" (SN: 10/3/87, p.220) was a good exposition of the usefulness of even very simple computer models of natural processes. It might have pointed out that most of the models discussed could easily be explored by anyone with access to a home computer. However, apparently unnoticed by the author, the article also illustrates the potential pitfalls of carelessly applied models.

The sequence of diagrams appears to indicate that a forest fire will tend, as the probability p of igniting neighboring cells grows from 0.51 to 0.75, to burn first as a fractal blob, then a rough circular area, then . . . a square? This is an artifact of the rectangular grid, as is easily shown with graph paper and a pencil.

Suppose for simplicity that p is 1.0: A cell with a burning neighbor always catches fire itself. (Perhaps a very dry windy day?) Then for $t = 1, 2, 3$, the "fire" will grow:

```

      3
     3 2 3
    . . 3 2 1 2 3 . . .
     3 2 3
      3
    
```

Obviously this tells us a lot more about graph paper than about forest fires. The lesson is important: For many values of p the results of the model may be meaningful; for values of 0.75 and larger, they are not. Everyone is aware that a model may be misleading if relevant factors (like wind) are omitted; this kind of error, while less familiar, is no less serious.

Redshift paradox

There appears to be a paradox in the application of the redshift to very distant objects such as quasars ("Breaking the redshift-4 barrier," SN: 10/17/87, p.254). If we were 18 billion light-years away from the quasar when the light we are now seeing started, wouldn't it have taken more than 18 billion years for the quasar to reach the state it had at the time the light started its journey to us? This would make the universe more than 36 billion years old and the quasar at least middle-aged at the time the light started on its way to us.

I realize that relativity theory will alter this simple argument. Unfortunately, I have never seen mention of, much less a satisfactory

explanation of, this apparent paradox. The fundamental importance of these concepts would seem to warrant a detailed analysis.

*John Sinnette
Tustin, Calif*

The redshift in the quasar's light gives a velocity by way of the Doppler shift formula. That velocity translates to a distance by way of Hubble's relation. In units of light travel time, that distance is 18 billion light-years, provided one uses a Hubble constant of 50 kilometers per second per megaparsec. The other popular value for the Hubble constant, 100, would yield 9 billion light-years. Until we get a measurement of the Hubble constant on which everybody agrees, we will continue to have these discrepancies.

Taking the value of 18 billion light-years means that we are seeing light that left the quasar 18 billion years ago; thus we are seeing it as it was and where it was 18 billion years ago. There is no reason to assume any existence for the quasar previous to that moment. It could have formed just then. We assume, however, that it could not exist before the beginning of the universe, and other evidence indicates that, given a Hubble constant of 50, the universe began about 20 billion years ago. That means that if we could see the actual Big Bang, it would appear with a redshift translatable to 20 billion light-years away.

What we see of distant objects depends on our distance from them in both space and time. In cosmology, as in Einsteinian relativity, the two are not separable, and we cannot say anything about the existence or condition of a given object at any epoch before (or after) we can see it.

— D.E. Thomsen

The Hyperactive Child, Adolescent and Adult

By Paul Wender

Attention Deficit Disorder Through the Lifespan

How do you know if your child or adolescent is hyperactive? Are you hyperactive yourself? What are the symptoms? Is there anything you can do? These are some of the questions Wender addresses in **The Hyperactive Child, Adolescent and Adult**, a practical guide and the first to trace hyperactivity through the lifespan. A leading psychiatrist and researcher, Wender has had extensive experience treating patients with Attention Deficit Disorder (a general disorder of which hyperactivity is one symptom). Here he covers not just excessive activity, but all the symptoms exhibited by ADD patients, and demonstrates how the disorder can change with age. Comprehensible and easy-to-use, the book provides parents, teachers and medical professionals with information needed to find help and to deal with the special emotional and behavioral problems of the ADD patient.
