

Floating Factories and the Fisheries

By LEWIS RADCLIFFE

As Deputy Commissioner of Fisheries, in the U. S. Department of Commerce, Mr. Radcliffe writes on fisheries with much authority.

Fishing excursions of our boyhood days were largely limited to the places we could reach by walking or driving old Dobbin. The advent of the automobile and the era of good roads has made the inaccessible places accessible and now one may fish on the other side of the continent. Except for stocking his vessel with a fare of salt fish, the demand for which has now largely vanished, formerly the commercial fisherman ventured only such distances from landing ports as he could return with a stock of fresh fish. Somewhat tardily the fisherman is seeking the aid of science—engineering, technology and chemistry. Thus he is developing ways of greatly expanding his sphere of operation. This effort to make available more distant sources of supply is most commendable.

The better insulation of the holds of the fishing vessels and the development of refrigeration machines suitable for installation and operation on board ships have greatly increased the distance the fishermen may go from his home port. California fishermen are enabled to take much greater toll of the fish supply off the coasts of Lower California; salmon are brought to this country from Kamchatka, the French have built a vessel for operation off the African coast and other European countries with a diminishing supply in the North Sea and around Iceland are now drawing upon the fishery resources of Greenland. The day is at hand when the fishermen may supply our table with aquatic delicacies from the remote corners of the earth.

Norwegians have perfected whaling ships capable of operating in the Antarctic, thousands of miles from their home port. The ship is fitted with a false bow which can be tilted downward into the water to serve as a runway up which one of these huge mammals may be drawn to be cut up. Machinery aboard extracts the oil from the blubber and converts the carcass into fish meal. These ships are independent of a land base and having filled their storage tanks with whale oil which is in special demand by soap-makers, may steam to whatever world port holds forth the best promise of a profitable market for their cargo. In recent years the number of whaling

companies has increased rapidly and no ocean area is exempt from whaling operations. In excess of 10,000 whales are killed annually, the maximum yield of oil being reached in 1923, amounting to 44,000,000 gallons. Millions of gallons of whale oil now find a ready market in this country.

This freedom of operations without restraint on the high seas has aroused the fear of intelligent observers that whales may soon become commercially extinct. The only possible control of such operations must be found in international agreement. Such a solution is now being sought by no less

PSYCHOLOGY

Tells How Mind Works

The scientific investigator should apply his science to the improvement of himself, Dr. William E. Ritter, president of Science Service, declared in a lecture before the School for Social Research in New York. Dr. Ritter, who spoke on how the scientific investigator uses his mind, stated that the conduct of human beings is about the most important subject for scientific research.

The trained scientist uses his mind as effectively as the opera singer uses his voice, or as effectively as the circus performer handles his body, he pointed out.

The scientist, who is often pictured as cold and matter-of-fact, needs imagination as much as the artist does, and would be helpless without it, Dr. Ritter said. The scientist, however, is bound by the rules of his game far more rigidly than the artist, because he must check the imagined things against real things more rigorously than the poet or novelist.

"This ability to use the mind for framing imaginary or hypothetical answers to questions, and then to work tirelessly year in and year out, if need be, to prove whether the imaginary answers do or do not correspond to the objective realities in the case is exceedingly far-reaching in its significance for the discovery of truth, and for human welfare," he stated.

The investigator must train himself intensively if he is to be a specialist in using his mental processes and his sight, hearing, and other senses, and if he is to direct his interests and emotions toward scientific achievement, Dr. Ritter showed.

Apes To Talk With Fingers?

A chimpanzee might be taught to talk with its fingers, as deaf people talk, more easily than it could be taught to imitate sounds of human speech, in the opinion of Dr. Robert M. Yerkes and Margaret S. Child, of the Institute of Psychology at Yale University.

Several scientists who have observed and studied higher apes have tried to teach them to say words, but without much success, these psychologists state in reporting in the *Quarterly Review of Biology* what is now known about anthropoid behavior.

"Perhaps the chief reason for the ape's failure to develop speech is the absence of a tendency to imitate sounds," Dr. Yerkes explains. "Seeing strongly stimulates to imitation, but hearing seems to have no such effect."

He believes that the sounds made by apes are not language, but are primarily emotional expressions, which are not learned by imitation.

A French scientist, Louis Boutan, who observed a female gibbon for five years, has concluded that a young child who has not learned to speak, works like the gibbon. A child who is beginning to talk no longer works like the ape but directs its efforts along a definite line, like a man. The difference, according to this investigator, is not due to the age of the child, but the development of language, which the ape lacks.

Both scientific and popular interest in the higher apes has increased steadily and greatly in the first quarter of the present century, the psychologists report.

ENGINEERING

Forty-Knot Liners

New York to Cherbourg in four days, to Naples in five days, and Italy to Buenos Aires in seven days, is the prospect of Italian shipping interests. Two vessels capable of forty knots, which would enable these times to be made, are now being contemplated. They are to be called the *Rex* and the *Dux*, and are to have a displacement of 35,000 tons each. According to a statement attributed to Premier Mussolini, these ships will be possible as a result of a new and secret invention in machinery, which will give power without vibration. The premier also stated that only one class of passenger will be carried on these ships.

For School Use

Teachers, Professors, Librarians and Club Leaders should take advantage of

The Science News-Letter

This weekly publication is a living textbook—it vitalizes science study—it brings to classes the news of the world in science. Through our contact with the scientific world we cover

Every Field of Science

No book can give you the material we offer in the SCIENCE NEWS-LETTER as a year's subscription to this worthwhile publication contains enough scientific matter to fill five large books. Also the SCIENCE NEWS-LETTER gives information months and even years before it can be published in book form.

Multiple copies (10 or more) for class room use are 6 cents a week.

Kindly write us for samples and school year prices.

Washington, D. C.**

Floating Factories

(Continued from page 197)

an august body than the League of Nations.

A recent development on our own coasts had added emphasis to the dangers resulting from unrestrained operations on the high seas. California authorities have constantly striven to restrict the amount of sardines—so abundant off their coast—which shall be used by the reduction plants for conversion into oil and meal. This has been done so that the great sardine canning industry may have an ample supply to satisfy the demand for this food delicacy. This "war baby" promises to become a permanent state industry, and is now producing more than a million cases of canned sardines per annum.

BINDER COVERS

FOR SCIENCE NEWS-LETTER

Many subscribers have expressed a desire for a convenient binder in which to file their copies of the Science News-Letter. We therefore have prepared an attractive and durable loose-leaf binder-cover of gray leather-like stock, printed in dark green and complete with fasteners. Each binder-cover will hold one volume (six months or 26 issues).

To facilitate punching the issues of the Science News-Letter to fit this binder-cover, a pattern showing where holes should be placed appears each week on the back cover page.

To obtain a binder-cover, send 20 cents in stamps (make them 2s, please), together with your name and address (please print) to

A huge yellow flower found in the jungle of Sumatra is three feet in diameter.

The first permanent photographic negative ever made is in the Science Museum in London.

The popular belief that snakes should be kept on ice is unfounded, as snakes are creatures of warm climates.

A short time ago a Nevada corporation anchored a fully equipped floating reduction plant within the limits of Monterey Bay but three miles offshore and proceeded to take sardines outside the three-mile limit for reduction purposes. The State Fish and Game Commission promptly took action and filed suit for a permanent injunction to restrain the company from continuing operations and this has been granted.

The menace still remains, and unless some form of international cooperation is evolved we may have another "rum row" off our coasts busily engaged in mopping up the fish supply with utter disregard of the needs for conservation and bootlegging the manufactured products into any port where they can find safe entry.

The most novel development in floating fish factories is that of the "Calgary," a French vessel of over 2,600 tons. This vessel is being provided with powerful refrigeration equipment and three large cold storage compartments with a capacity of 800 tons of fish. There are six retorts on board. One will be used for cooking lobsters and crayfish; another for making gelatin; two, capable of handling 40 tons of fish and fish waste per 24 hours for conversion into oil and fertilizer; and two others with a capacity of five tons each for the steam extraction of oil from the livers of sharks and rays. There are two oil storage tanks, one of 26,000 gallon capacity for storing fish oil and one of nearly 400 gallons for liver oil. Although it is proposed to operate the vessel off the west coast of Africa it has been suggested that the vessel may visit Iceland, Greenland, and even North Atlantic fishing banks adjacent to our own coasts.

The power of science in making far distant resources available is well illustrated by these developments. Unless subjected to proper international control, these same developments may encompass the ruination of important aquatic resources and leave us poorer than before.
