

tails and long necks at the ends of which sit ridiculously small heads. They float, swim and feed in the waters with unhurried languor, for they are sluggish, cold-blooded creatures. They enter by the tens of thousands, huddling close together as reptiles do, and filling every lagoon as far as the eye can see. Myriads of them cluster the watery landscape like city-throngs crowding a popular beach during a heat-wave.

A Great Change

Now Mother Nature slowly changes the stage setting. The lakes dry up and the swamps vanish. The sauropod dinosaurs become more and more concentrated as they are pushed together in huge herds by the drying up process which changes lakes into ponds, ponds into pools and lastly into quickly drying puddles. The sauropod dinosaurs are water animals and the disappearance of the water is their death sentence. They cannot migrate because of their great bulk. Some starve to death—others are stranded in the mire that follows the receding water—while others, in their frenzied rush to escape destruction, struggle to solid land, only to be killed by the flesh-eating monsters that skulk around the pools and live high, for a time, on the hapless sauropods.

A clear-cut cross section of this large scale drama is now being uncovered in the Red Gulch Quarry. The hill in which the skeletons rest was once upon a time the bottom of a large lake that shrank into a tiny pond. It is perfectly evident that it is the bottom of that pond we have stumbled upon—the very spot where a dozen or more sauropods made their last and futile stand against fate—one of the last remnants of hundreds, perhaps thousands, of these beasts that lived and thrive in that very spot until the lake began to dry up and the relentless battle started in which the weak were swiftly killed while the strong survived for only a short time.

May Find Victors, Too

We have not found any as yet, but I would not be at all surprised if, dove-tailed in among the sauropod bones, we should find remains of the carnivorous dinosaurs that, undoubtedly, came to the lake to feed on the sauropods and eventually died of starvation when their victims sank into the bog.

Pieces of fossil wood found 200 feet underground near Placerville, Calif., have been identified as trees of the Miocene epoch, 11,000,000 years ago.

PHYSICS

Old Violin Makers' Secrets Revealed by X-Ray Analysis

Treatment and Varnish Are Not So Important As Is Selection of Wood for Back, It is Found By Physicists

THE SECRET of the tone of violins fashioned by such famous makers as Stradivarius, Amati, Pique and others, has been discovered.

Through X-ray studies of structure of wood in violins of various origins, Dr. K. Lark-Horovitz and W. I. Caldwell, physicists of Purdue University at Lafayette, Ind., have found that proper selection of wood is more important for the quality of the instrument than treatment and varnish.

By careful selection of wood as a result of the Purdue researches it will be possible, it is believed, to make modern violins that are the equal in tone to those by famous makers.

The results of the Purdue researches were communicated to and published by the British scientific journal, *Nature*.

Definite fiber structure was found in spruce wood used for the top of violins, but the pattern of molecules revealed by the X-rays when they were turned on the wood used for the back showed that the woods, mostly maple, are different for instruments of different tone quality. Instruments with an even and smooth tone quality, especially for higher pitch or E-string, show an almost complete lack of orientation in the wood used for the backs.

Makes Tone Harsh

Violins with a harsh tone quality in general, weak response and shrill upper register showed a marked fiber structure in the maple used in the construction of their backs.

"Our investigation indicates," the Purdue scientists concluded, "that for a fine instrument only the top should be characterized by different velocity of sound in different directions, whereas the velocity of sound in the back should be the same in all directions so as to produce the best results."

Not since the French investigations of Savart over a century ago had there been adequate inquiry into the choice of material for violins. It had been stated repeatedly that age, treatment and varnish change the character of the

wood, but the studies of Dr. Lark-Horovitz and Mr. Caldwell indicate that this is not the case.

Modern makers of fine violins by using X-ray analysis of woods and following the construction methods revealed by the new studies are expected to produce modern instruments that rival in usefulness the old violins valued at many thousands of dollars.

ENGINEERING

Don't Buy "Gas Savers" Warns Bureau of Standards

DON'T BUY "gas savers," "grease absorbers," or "burner protectors." They don't save a penny; in fact, they usually cost more by increasing gas bills and many of them causes headaches, or worse effects of that stealthy and dangerous poison, carbon monoxide.

The National Bureau of Standards has conducted an investigation of a number of gadgets and appliances that were sold over the doorsill by salesmen who lauded them to the skies in extravagant claims of their value. The results of this research called for a warning against such purchases, which the Bureau issued.

All of the "gas savers," it stated, affected the operation of a satisfactory gas range in such a way as to increase the tendency to form carbon monoxide, which even in very small amounts is injurious to health. Although agents sometimes boasted of a reduction in gas bills as high as 30 per cent., none of the attachments tested appreciably increased efficiency while some of them considerably increased the amount of gas needed for certain purposes.

Lower Efficiency

The "burner protectors," the report continued, keep the burners clean but do so at the expense of cooking efficiency. None of the water backs tested proved satisfactory while some of them caused the formation of carbon monox-

ide. Attractive solid tops and all the varied things which are placed in the flues tended to prevent complete combustion and to lower efficiency and were an actual menace to health. A flue is constructed by the manufacturer to be as small as possible and still allow complete burning of the gas, and when it is obstructed further to keep more heat in the stove or for any other purpose, a

dangerous condition frequently results.

"The 'grease absorbers,' " scientists observe, "should be called grease diffusers, because they merely distribute the grease more uniformly around the kitchen. Those that are filled with steel wool or other material in such a way as to obstruct the passage of the flue gases may become dangerous."

MEDICINE

Cancer Caused By Virus Present in Even Normal Cells

New Theory of British Scientist Holds Disease Is Not Infectious But Develops From Irritation

WITHIN seemingly normal cells of human bodies, there is always a virus capable of causing cancer. Whether or not the disease develops depends upon whether a physiological "trigger" in the form of mechanical or chemical irritation sets free the virus.

This new theory of cancer with evidence for its support is presented by Dr. C. H. Andrewes of Britain's Medical Research Council.

Dr. Andrewes' report to the Royal College of Surgeons appearing in the *Lancet* is commended by the editor of the *Lancet* as "by far the most comprehensive survey" of the subject yet presented.

When irritants initiate malignancy, Dr. Andrewes believes, no virus enters the body. It has always been there, dormant, pending the trigger mechanism which sets off the malignant process. Such mechanical balance would explain the graduations from benignancy to extreme malignancy which are seen in tumors.

Like Fever Blisters

The development of cancer is seen as somewhat analogous to the formation of fever blisters. A mere rise in body temperature, such as caused by a fever, is enough to cause fever blisters in about every other person so afflicted. The herpes simplex virus seems to be liberated by the heat and causes the face eruption.

Dr. Andrewes' theory, according to the editorial, confirms the fact that cancer is not infectious in the conventional sense. In other words, although caused

by a filtrable virus it is not infectious like infantile paralysis, for example, which is also caused by a filtrable virus.

Many cancer students have thought that mammalian cancers are an apparently different class of tumors from the filtrable fowl tumors, but Dr. Andrewes

does not agree. He thinks the two kinds are really alike. The only way in which filtrable tumors of birds differ from cancers of men and other mammals lies in the fact that the causative agent of the fowl tumors can be demonstrated apart from the cells it normally inhabits, he concluded from his investigations.

The causative agents of cancer have properties so like those of the known viruses that excluding them from the virus group is unjustified, in Dr. Andrewes' opinion.

The natural history of other viruses readily explains the production of tumor growth phenomena, he stated. Many viruses multiply within the cells of the body and once they have gotten into these cells they cannot be neutralized by external antibodies.

Glass cotton, glass silk, and glass wool are novel fibers which have a variety of industrial possibilities.

Rosie, a Yellowstone Park bear, emerged from hibernation this spring with four black cubs, the biggest family of bears ever credited to one mother.

TO CATCH THE STARLIGHT

This giant "mousetrap" is really the framework of a new observatory dome to house the large telescope which will be located on the summit of Mt. Locke, in southwestern Texas. Arc-welded steel bracing will protect the structure against possible earthquake shocks. It is shown here as it was pre-assembled in Cleveland, Ohio, before its 1500-mile journey to Texas. The dome, which is 62 feet in diameter and 73 feet high, was constructed by the Paterson-Leitch Company under the supervision of the Warner and Swasey Company, designers. An electrically-moved observing bridge will give the observers access to all parts of the dome and the telescope it encloses.
