

production and maintained their body temperature.

When the dogs breathed gas mixtures with lowered oxygen content through their masks the shivering soon stopped and their metabolism returned to the basal level and the body temperature fell about two degrees Centigrade per hour. Greatest total drop in temperature was six degrees Centigrade.

The temperature fell gradually, reported the Harvard scientists, until the dogs were switched over to breathing the air in the cold room. Then the body's metabolism suddenly increased four times and within a half hour the body temperature was back to normal.

"The ability of the dog to withstand low oxygen depends more on the toughness of his central nervous system than on an unusual ability to take oxygen in the lungs," conclude the scientists.

Novel Oil Prospecting

A METHOD of oil prospecting by measuring temperatures in the earth at depths of 100 to 200 feet was described by Melvin C. Terry.

It is not necessary to take the temperature measurements at extreme depths because the intrusion of high conductivity materials will disturb the pattern of normal temperature gradients.

Working over the ground of producing Texas oil fields at Hastings and Friendswood, it was found that the line of constant temperature at 23 degrees Centigrade ran about 100 feet higher over the oil salt domes than it did in the region between them.

New Theory on "Hot Spots"

THE TRADITIONAL explanation of the skin's sensitivity to heat and cold was discounted by new findings reported by Lehigh University's Dr. William LeRoy Jenkins, instructor in psychology.

The thought that temperature sensitivity of the skin was concentrated in small warm and cold spot receptors arose from the discovery that the locations of these spots could be mapped with a small stimulator.

Dr. Jenkins has carried forward the mapping technique and by the process of seriatim, or repeated mapping, has found that the single warm and cold spots do not exist.

"Seriatim mapping," Dr. Jenkins declared, "reveals hills and valleys of sensitivity. Warm and cold spots are found

only in clusters and mapping with smaller and smaller sizes does not resolve these clusters into discrete units; they simply disintegrate without being resolved."

As a new and better way to explain the skin's temperature sensitivity, Dr. Jenkins proposes a "concentration hypothesis" which suggests that the sensitivity depends primarily upon the concentration of the receptors. Where the receptors are highly concentrated, the skin's sensitivity is high. Where they are sparse, the sensitivity is low. According to this view, the traditional warm and cold spots are merely peaks of sensitivity and do not mark the locus of individual receptors.

PUBLIC HEALTH—ECONOMICS

Drought in Far East Creates Serious Food Problems

DROUGHT in Japan and Korea, severely curtailing production of vegetables and rice, has created serious food problems, reports Kurt Bloch, writing in the *Far Eastern Survey* (Oct. 25). The drought has also resulted in severe damage to the fresh-water fisheries, while the production of sea fisheries has been cut

down by restriction on gasoline sales to the fishermen, forcing them to give up use of motor power for slower means.

In the meantime, the occupied portions of China have begun to present serious competition for existing food supplies. North China has always been a heavy wheat-consuming country, but before the outbreak of hostilities had got on a self-sustaining basis so far as this grain was concerned. Now North China imports 800,000 tons of wheat in a year—which means a staggering load on "yen bloc" finances.

GENERAL SCIENCE

Scientists Shop and Pack For Year in Antarctic

See Front Cover

HOUSEWIVES will appreciate the problem of the U. S. Antarctic Expedition setting sail for the other end of the earth: Shopping for supplies for more than a year for two little communities, two base camps, plus exploring parties on the trail—1200 tons of everything well-ordered pioneering households will need, including the houses.

All are boxed securely against Antarctic cold and packaged so strong men can unload under adverse conditions.

COAL, TANKS AND MEN FOR EXPLORATION

The two leaders of the base camps to be laid down in Antarctica by Uncle Sam, Richard B. Black, East Base commander (left) and Dr. Paul A. Siple, West Base commander, inspect the converted Army tanks that will be used as "iron dogs" for snow travel. In the background, the "North Star," being loaded at Boston Army Base. Piles of bagged coal at left.
